

# MATE 318

Spring 2025

## Homework #6

**Due: May 30<sup>th</sup>, 2025**

Group submission (up to 3 students per group) is allowed.

1

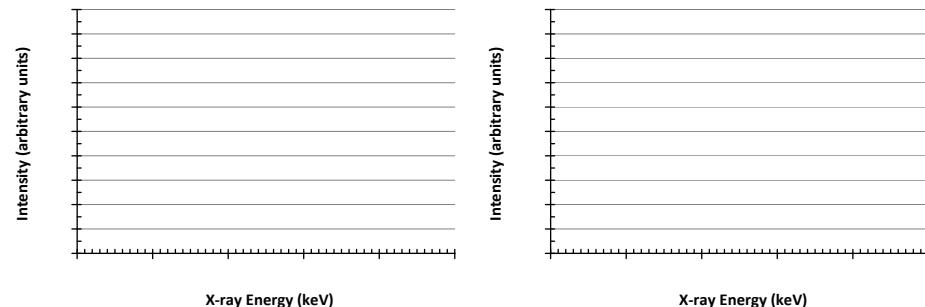

### Question 2

EDS counts of two Ti-Al-Nb ternary alloy samples one with a composition of 45 at.% Al and 4 at.%Nb, and the other with unknown composition are given in the table below. Determine the composition of the unknown alloy.

		Ti K $\alpha$	Al K $\alpha$	Nb K $\alpha$
Reference Sample	Comp. (at.%)	51	45	4
	EDS Count	15228	6335	918
Unknown Sample	Comp. (at.%)	?	?	?
	EDS Count	14391	5132	831

### Question 1

- On the figures below, sketch as accurately as you can the K $\alpha$  x-ray energy spectrum measured with an EDX detector in an electron microprobe for a sample consisting of a homogeneous solder alloy of composition 37 wt.% Pb and 63 wt.% Sn. Assume an electron beam energy of 90 keV was used. State other assumptions you make (if any).
- How would the spectrum differ if the electron beam energy was 45 keV? Why?

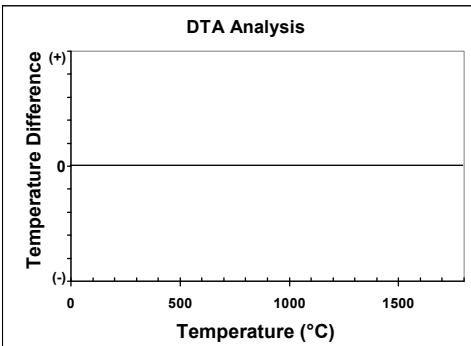

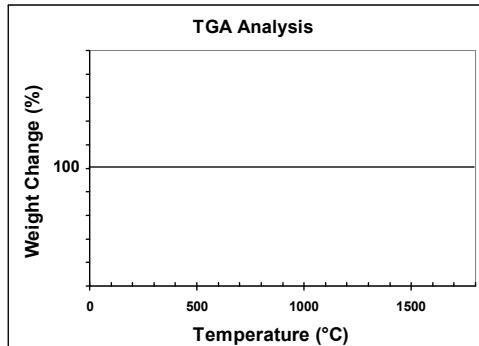

### Question 3

A WDS spectrometer which uses (200) planes of LiF as the analyzing crystal detects x-ray peaks from a sample at  $24.31^\circ$  and  $43.02^\circ$  in  $\theta$ . Assuming that the detected peaks are K $\alpha$  peaks, determine which elements are present in this sample.

$$d(200) \text{ of LiF} = 0.2015 \text{ nm}$$

#### Question 4

A sample of pure iron has been analyzed in ambient air using a combined TGA-DTA instrument with a heating rate of  $1^{\circ}\text{C}/\text{min}$ . Schematically draw the TGA and DTA curves you would expect for the temperature range of  $0^{\circ}\text{C}$ - $1600^{\circ}\text{C}$ .

#### Question 5:

The load vs. displacement curve given below belongs to a nanoindentation test performed on a hard coating using a diamond tip with perfect Berkovich geometry. Find the hardness (H) and elastic modulus (E) values of this coating in GPa.

For diamond take E as 1000 GPa and the Poisson's ratio as 0.06. Take the Poisson's ratio of the coating as 0.21. Take  $\beta$  as 0.75.
